

# DATABASE MANAGEMENT SYSTEMS

Associate Professor Dr. Raed Ibraheem Hamed

University of Human Development, College of Science and Technology  
Computer Science Department

2015 – 2016

# Points to Cover

- ▶ Models of Reality
- ▶ Why Use Models?
- ▶ A Map Is a Model of Reality
- ▶ A Message to Map Makers
- ▶ Use a DBMS when this is important
- ▶ Data Modeling
- ▶ Process Modeling
- ▶ Database Design
- ▶ Abstraction

# Database as a Model of Reality

A database is a model of reality. It represents a set of views, held by a community for users, on how they retrieve and process information. This model should be accurate and at the same time simple.

- DDL: Data Definition Language
- DML: Data Manipulation Language

# Why Use Models?

- Models can be useful when we want to examine or manage part of the real world
- The costs of using a model are often considerably lower than the costs of using or experimenting with the real world itself
- Examples:
  - ❖ airplane simulator
  - ❖ nuclear power plant simulator
  - ❖ flood warning system
  - ❖ model of US economy
  - ❖ map

# A Map Is a Model of Reality

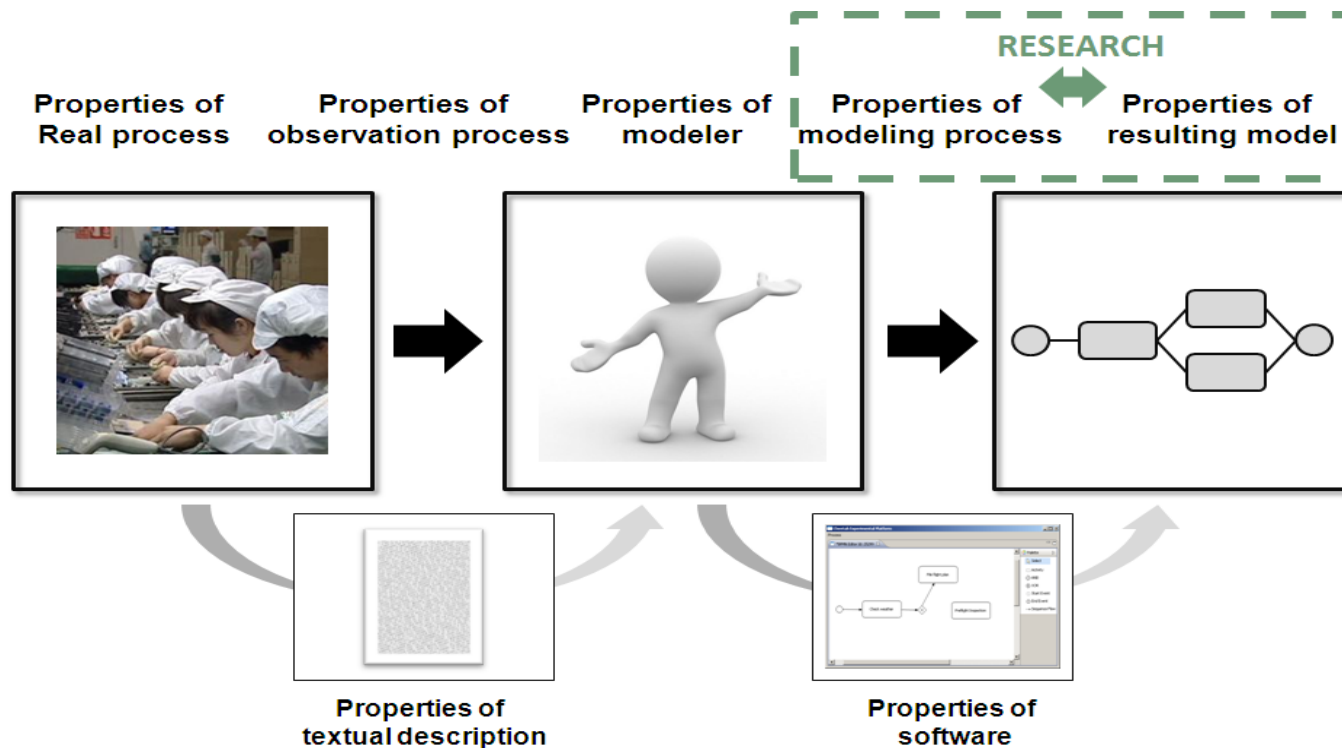

# A Message to Map Makers

- A model is a means of communication
- Users of a model must have a certain amount of knowledge in common
- A model on emphasized selected aspects
- A model is described in some language
- A model can be with error
- A message to map makers keep all the details.

# Process Modeling

Process modeling is a technique for organizing and documenting the structure and flow of data through a system's processes.

# Database Design

**The purpose of database design is to create a database which**

- is a model of structures of reality
- supports queries and updates modeling processes of reality
- runs efficiently

# Data Abstraction

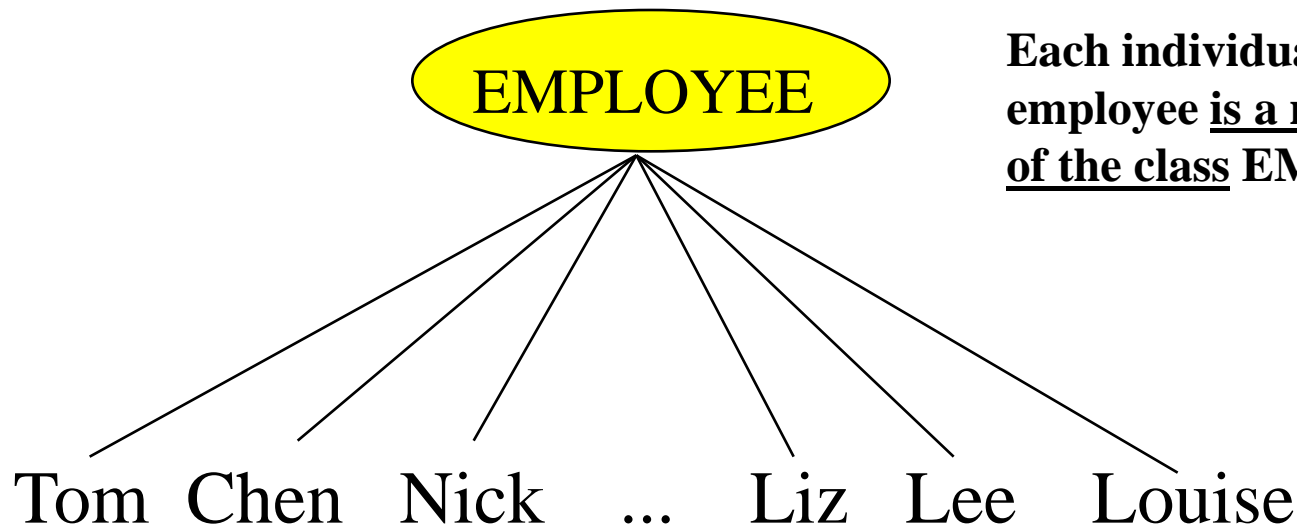

**Data abstraction** is the reduction of a particular body of **data** to a simplified representation of the whole. **Abstraction**, in general, is the process of taking away or removing characteristics from something in order to reduce it to a set of essential characteristics.

We will discuss three kinds of abstraction:

- Classification
- Aggregation
- Generalization

# Classification Abstraction

In a classification we form a concept in a way which allows us to decide whether or not a given phenomena is a member of the extension of the concept.

Each individual  
employee is a member  
of the class **EMPLOYEE**

# Classification Abstraction (contd.)

January, February etc. are members of the class “MONTH”

# Aggregation Abstraction

In an aggregation we form a concept from existing concepts. The phenomena that are members of the new concept's extension are composed of phenomena from the extensions of the existing concepts

# Aggregation Abstraction

Root class: CAR

Component Classes: Chassis, Drive-Train, Other Systems, Wheels

Root class: Wheels

Component Classes: Tires, Tubes, Hub-Caps

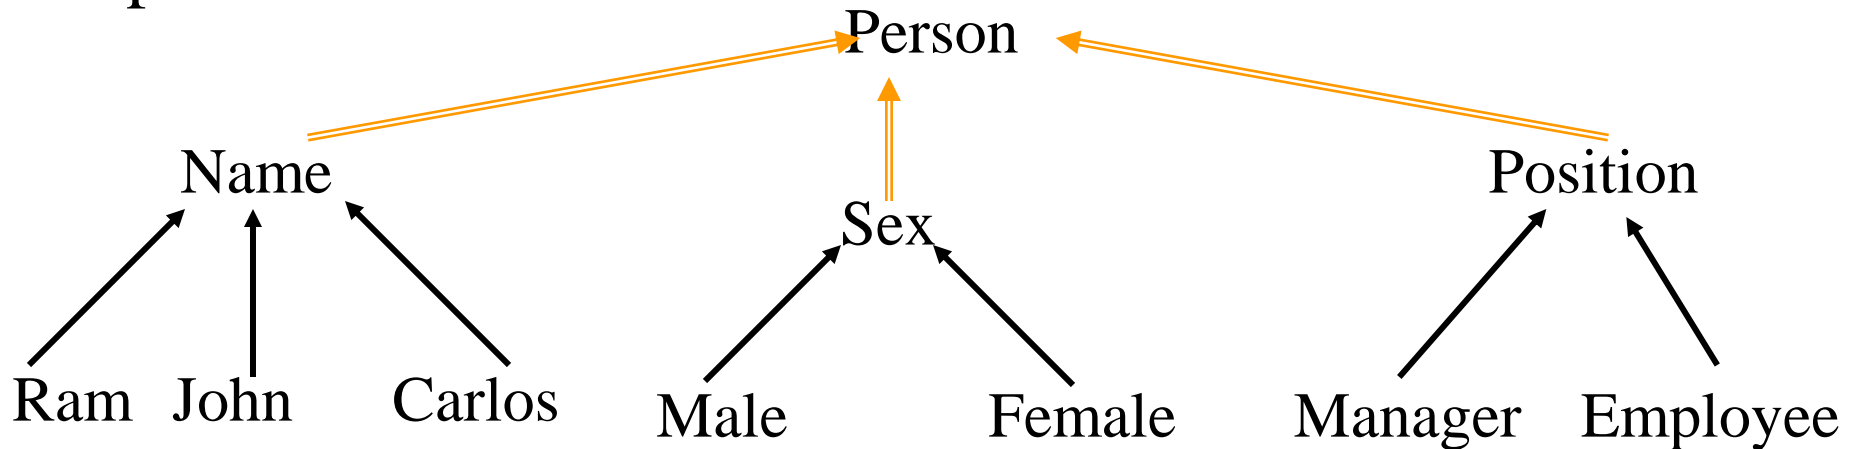

# Classification and Aggregation

Classification and Aggregation are used to build schemas

Example: class Person

Representation:

Name, Sex, and Position aggregate into Person. They are classes themselves.

Ram, John, Carlos are classified into Name or Name is a classification of Ram, John, Carlos

# Generalization

In a generalization we form a new concept by confirming common aspects of existing concepts, leaving out special aspects

# Types of Abstractions

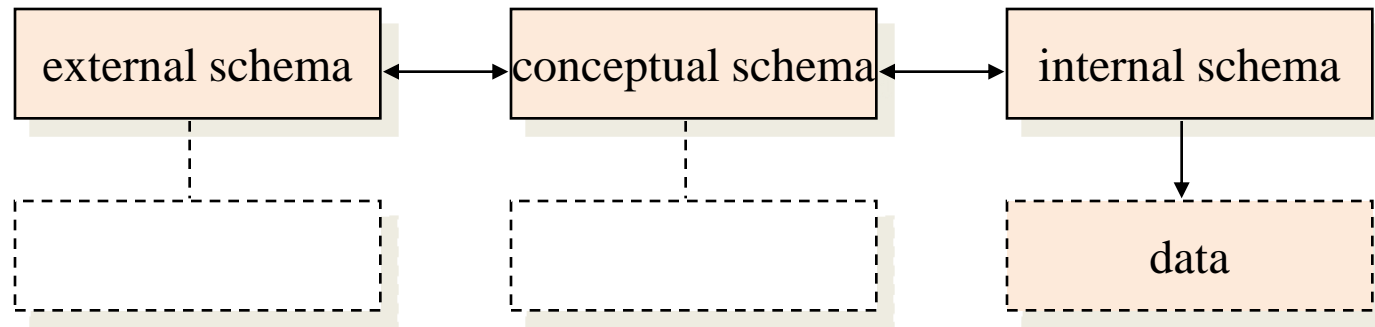

Classification	A is a <u>member of</u> class B
Aggregation	B,C,D are aggregated into A A is <u>made of/composed of</u> B,C,D
Generalization	B,C,D can be generalized into A,

# 3-Level DB Architecture

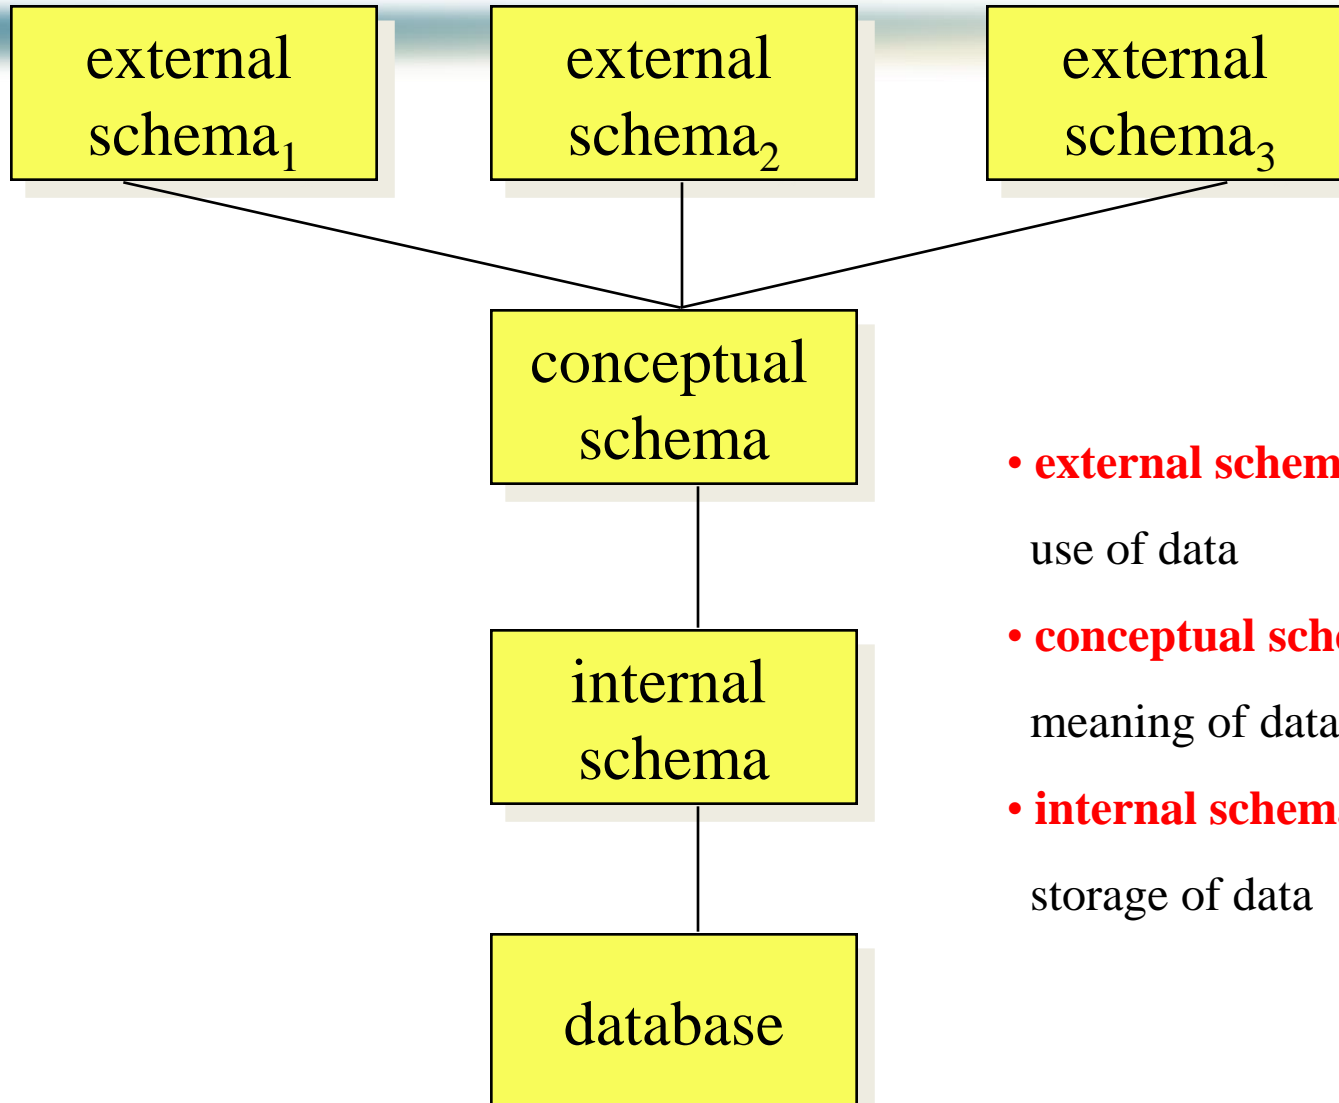

- a database is divided into **schema** and **data**
- the **schema** describes the **types**
- the **data** describes the **extension (data)**

# 3-Level DB Architecture

# 3-Level DB Architecture

- **external schema:**  
use of data
- **conceptual schema:**  
meaning of data
- **internal schema:**  
storage of data

# Thank you

???
